Permanent Magnet DC motors

We consider permanent magnet DC motors. Other kinds include AC motors and brushless DC motors.

A model for the motor torque is $\tau = K_m i_a$, if the flux in the motor is constant. The current is generated by a voltage source, and has dynamics

$$L \frac{d}{dt} i_a + R i_a = V - V_b, \quad (1)$$

where L is the motor inductance, R is the winding resistance, V_b is the back EMF and is proportional to ω_m , the motor speed.

PMDC Model

The dynamics governing θ_m are

$$J_m \ddot{\theta}_m + B_m \dot{\theta}_m = \tau_m - \tau_l / r \quad (2)$$

$$= K_m i_a - \tau_l / r \quad (3)$$

We can rewrite (1) and (5) as

$$(Ls + R)I_a(s) = V(s) - K_b s\Theta_m(s), \quad (4)$$

$$(J_ms^2 + B_ms)\Theta_m(s) = K_m I_a(s) - \tau_l(s)/r \quad (5)$$

We combine these equations to obtain

$$s((Ls + R)(J_ms + B_m) + K_b K_m)\Theta_m(s) = K_m V(s) - \frac{(Ls + R)}{r} \tau_l(s). \quad (6)$$

Fast Electrical Dynamics

The electrical time constant L/R is much smaller than the mechanical time constant J_m/B_m . So, we can divide by R and set L/R to zero, obtaining.

$$s \left((J_m s + B_m) + \frac{K_b K_m}{R} \right) \Theta_m(s) = \frac{K_m}{R} V(s) - \frac{1}{r} \tau_l(s).$$

Setting $u \leftarrow K_m V/R$, and $B \leftarrow B_m + K_b K_m/R$, we obtain the motor equation as

$$J \ddot{\theta}_m + B \dot{\theta}_m = u(t) - \frac{1}{r} \tau_l. \quad (7)$$

Combined Link-Actuator Model

Let's combine the motor m with the link l

$$J_m \ddot{\theta}_m + B \dot{\theta}_m = u(t) - \frac{1}{r} \tau_l \quad (8)$$

$$J_l \ddot{\theta}_l + B_l \dot{\theta}_l = \tau_l \quad (9)$$

Due to the gears, $\dot{\theta}_m = r \dot{\theta}_l$. We eliminate θ_l to obtain

$$(J_m r^2 + J_l) \ddot{\theta}_l + (Br + B_l) \dot{\theta}_l = ru \quad (10)$$

The main takeaway is that when r is large, then the link inertia becomes negligible compared to the motor's inertia.
